

Same simulated draw; same reported interval

$$e_T = \bar{Y}_T - s\mu_P \quad e_N = \bar{Y}_N - \mu_P$$

Score the fixed parameter

$$\hat{\theta} - \theta_P = f_N(e_T - e_N)$$

Score the sampled reference

$$\hat{\theta} - i_{\text{req}} = f_N(e_T - se_N)$$

Tumor-arm error is unchanged.
Reference-arm error is multiplied by s .

Reference-arm variance
at a halving ($s = 0.5$)
